Cable trays encounter ventilation

Overview

Cable trays and ventilation systems must be installed with sufficient clearance to avoid interference and ensure proper airflow. One of the main benefits of. When designing or installing cable trays in a building, one of the key factors to consider is the safety distance between cable trays and other systems, such as ventilation or drainage. It's not just about ensuring space for each system; the right safety distance is essential for preventing. Cables heat up for a few main reasons: Too Much Load: As we need more power, cables carry more electricity. If a cable carries more current than it's built for, it will get hot. A 600A feeder run in a solid-bottom tray, despite being 24 inches wide, can cause conductor temperature to exceed 90°C insulation rating within two hours of full load if NEC Article 392. The result is the percentage of tray reference area that is open or perforated and potentially available for airflow around installed cables.
