External grounding of the secondary power distribution box at the construction site

Overview

This section applies to grounding of transmission and distribution lines and equipment for the purpose of protecting employees.

Key Takeaways

The secondary power distribution box at a construction site must be externally grounded to provide a continuous, low-impedance path to earth, protecting personnel from electrical shock and ensuring proper operation of overcurrent devices.

Purpose of External Grounding

External grounding ensures that any fault current from the distribution box flows safely to the earth rather than through a worker, preventing electrocution and equipment damage. It stabilizes voltage during normal operation, limits unintended voltage from lightning or line surges, and establishes a reliable path for overcurrent devices to operate correctly (OSHA, NEC Article 250).

Key Requirements

Grounding Electrode Connection: The distribution box must be connected to a grounding electrode, such as a driven rod, metal water pipe, or concrete-encased electrode, using a grounding electrode conductor sized according to NEC Table 250. 66. Equipment Bonding: All metal parts of the box, including enclosures, panels, and conduit, must be bonded together to ensure electrical continuity and prevent potential differences that could cause shock.

System Grounding: The grounded conductor (neutral) of the secondary distribution system should be connected to the grounding electrode to stabilize system voltage and facilitate proper operation of breakers and fuses. Temporary Construction Considerations: For construction sites, temporary grounding must create an equipotential zone to prevent hazardous voltage differences between the box and surrounding conductive objects, as outlined in OSHA 1926. 962.

Installation Best Practices

Use a continuous, low-resistance conductor from the box to the grounding electrode. Ensure tight mechanical connections and corrosion-resistant materials. Verify grounding effectiveness with a ground resistance test, aiming for a resistance of 25 ohms or less for temporary construction setups.

Maintain clear labeling and accessibility for inspection and maintenance.

Safety Compliance

Following these grounding and bonding practices ensures compliance with OSHA regulations (29 CFR 1926 Subpart K) and NEC Article 250, reducing the risk of electrical shock, equipment damage, and regulatory violations. Proper grounding is critical for both employee safety and reliable operation of the construction site electrical system.
