Several circuits in the lighting distribution box

Overview

Distributing light safely To ensure maintenance, control and safety, it makes sense to divide them into separate circuits. For example, indoor and outdoor.

Key Takeaways

Multiple lighting circuits can be safely managed in a single distribution box by using separate breakers, proper wiring, and adherence to load and safety standards. Purpose of a Distribution BoxA lighting distribution box, also called a sub-distribution board or fuse box, is the central hub for distributing electrical energy to different lighting circuits within a building or area. It protects cables and devices from overloads and disconnects circuits in case of faults like short circuits, ensuring safety and stability of the lighting system.

Dividing lights into separate circuits allows for easier maintenance, better control, and integration of devices like timers or motion sensors.

Types of Lighting Circuits

Lighting circuits are typically low-capacity circuits, often rated at 6 amps, and can be arranged using either a loop-in system or a joint-box system. In a loop-in system, power runs from the breaker to the first light and loops to subsequent lights, while in a joint-box system, wires run to junction boxes before reaching the fixtures. Multiple circuits may be used in important areas to ensure some lighting remains operational in case of a phase failure.

Wiring Multiple Circuits

Parallel Wiring: All fixtures must be wired in parallel to maintain full voltage across each light and prevent one failure from affecting the others. Pigtailing: In junction boxes, incoming power is spliced with wires going to the next fixture and a short wire to the fixture itself, ensuring proper distribution. Switch Loops: Power can be fed to the switch or the first fixture, with modern code requiring a neutral in the switch loop, often using a three-conductor cable.

Safety and Load Management

Circuit Breakers: Each circuit should have its own breaker to prevent overloads. Continuous load should not exceed 80% of the breaker's rated capacity (e.g., 12 amps for a 15-amp breaker),. Box Fill: When multiple circuits share a box, ensure the box is large enough to accommodate all wires, devices, and grounds while keeping neutrals separated.

RC

D Protection: Residual current devices (RCDs) are recommended, especially in damp or outdoor areas, to protect against electric shock.

Practical Considerations

Separate Circuits for Different Areas: Indoor and outdoor lighting, or high-use areas, may benefit from separate circuits for convenience and safety. Professional Consultation: For complex setups with multiple switches, 3-way or 4-way configurations, or mixed amperage circuits, consulting a licensed electrician ensures compliance with local codes and safe operation. By following these guidelines, multiple lighting circuits can coexist safely in a single distribution box, providing both operational flexibility and protection against electrical hazards.
