Wires are connected in parallel to the distribution box

Overview

Domestic electric appliances are connected in parallel electric circuits. The sockets consist of three points one connected to a live wire, a neutral wire, and the earth wire.

Key Takeaways

In a distribution box, wires are connected in parallel so that each circuit receives the same voltage independently, typically using busbars or terminal blocks rather than unsafe jumpers.

Understanding Parallel Connections

In parallel wiring, each load or circuit is connected across the same voltage source, creating multiple paths for current flow. This ensures that if one circuit fails, the others continue to operate normally, unlike series connections where a single failure interrupts the entire circuit. In a distribution box, this allows multiple branch circuits to draw power independently from the main supply.

Practical Implementation in a Distribution BoxMain Supply Connection: The phase (live) and neutral wires from the main supply are connected to the input terminals of the main MCB (double-pole for single-phase systems) or main switch. Branch Circuit Distribution: From the main MCB, power is distributed to individual branch MCBs or RCCBs. Each branch receives the same voltage, forming a parallel connection.

This is often done using busbars or single-bolt parallel groove connectors with heat shrink sleeves to safely join multiple wires. Avoiding Jumpers: Older methods used jumpers—wires connecting the top of one MCB to the next—but this is unsafe because the first wire carries the sum of currents from all downstream circuits, risking overheating and fire hazards. Modern standards prohibit this method.

Neutral and Earth Connections: Neutral wires from all branch circuits are connected to a neutral busbar, and earth wires are connected to the earth busbar, ensuring proper grounding and safety.

Key Safety Considerations

Use proper connectors: Single-bolt parallel groove connectors or busbars are recommended to handle multiple wires safely. Maintain spacing: Ensure enough space between the main switch and branch MCBs for wire routing, and cover exposed areas with circuit breaker baffles if needed. Correct wire sizing: Each wire should be rated for the expected current of its branch circuit to prevent overheating.

By following these practices, each branch circuit in the distribution box operates independently at the same voltage, ensuring reliable and safe power distribution throughout the household or facility.

According to NEC Article 250, neutral and ground wires must remain separate in subpanels. Bonding (connecting) the neutral and ground should only occur in the main panel or at the first service

366.20 Conductors Connected in Parallel.

Joining conductors in parallel is like having two or more smaller conductors connected at each end to make one larger conductor. This is often done to make wire pulling easier.

Wiring of the Distribution Board with RCD (Single Phase Home Supply)

The Sub distribution board is connected and supplied from the Main Distribution Board through different wires and cables rated according to the load requirement.
